

INTERPROCESS COMMUNICATION

Topics

- INTRODUCTION
- The API for the INTERNET PROTOCOLS
- EXTERNAL DATA REPRESENTATION
- CLIENT-SERVER COMMUNICATION

4.1 Introduction

- A process can be: **Independent** process or **Co-operating process**.
- An **independent process** is **not affected** by the execution of other processes while a **co-operating process** can be **affected** by other executing processes.
- Processes running **independently**, will execute **very efficiently** but in practical, there are many situations when **co-operative nature** can be utilized for **increasing computational speed, convenience and modularity**.
- Inter process communication (IPC)** is a mechanism which allows processes to **communicate** each other and **synchronize** their actions.

Processes can communicate with each other using these two ways : **Shared Memory** or **Message passing**

4.1 Introduction

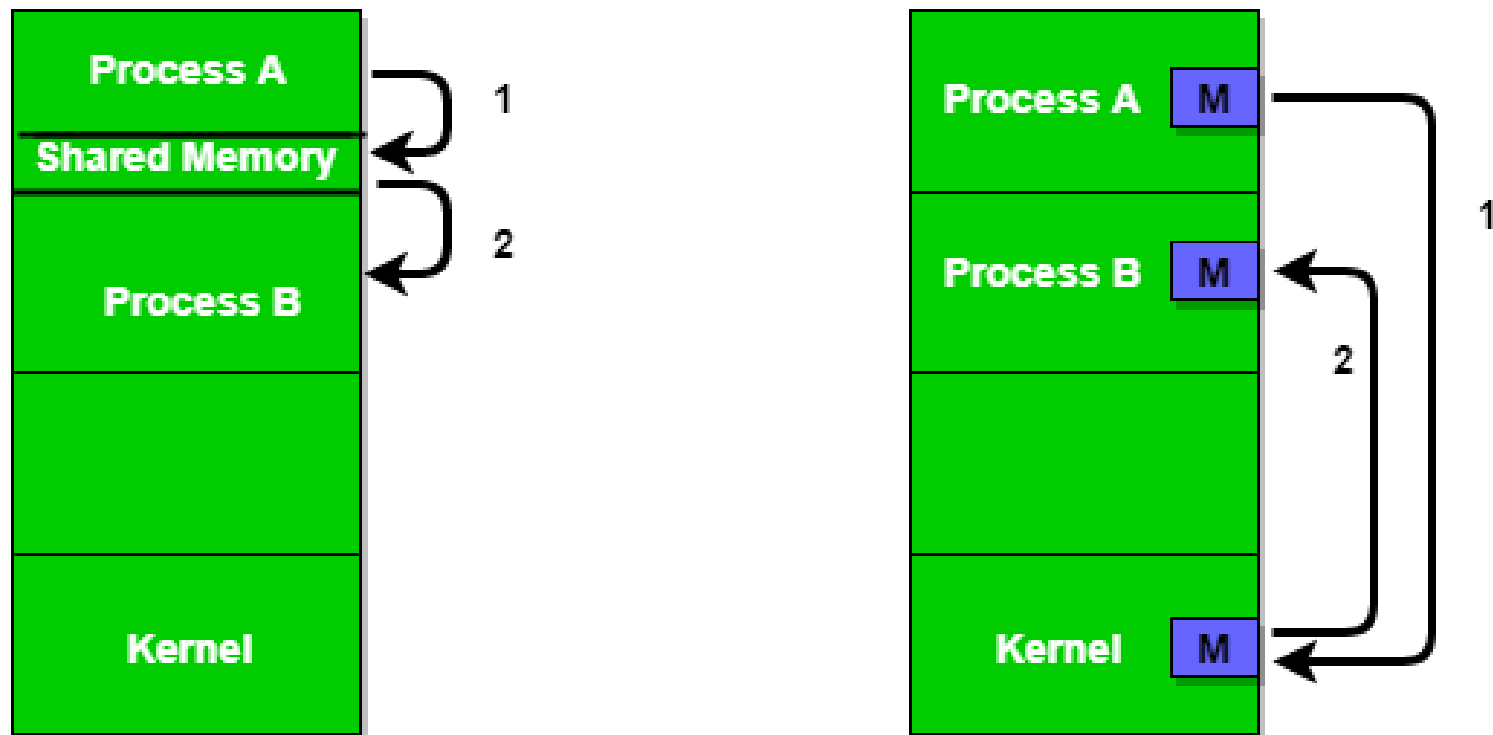

Figure 1 - Shared Memory and Message Passing

4.1 Introduction

- The java API for interprocess communication in the internet provides both **datagram** and **stream** communication.
- The communication patterns that are most commonly used in distributed programs:

- **Client-Server communication**

- ❖ The request and reply messages provide the basis for remote method invocation (RMI) or remote procedure call (RPC).

- **Group communication**

- ❖ The same message is sent to several processes
- ❖ **Group multicast** communication in which one process in a group transmits the same message to all members of the group

Introduction

- This chapter is concerned with middleware.

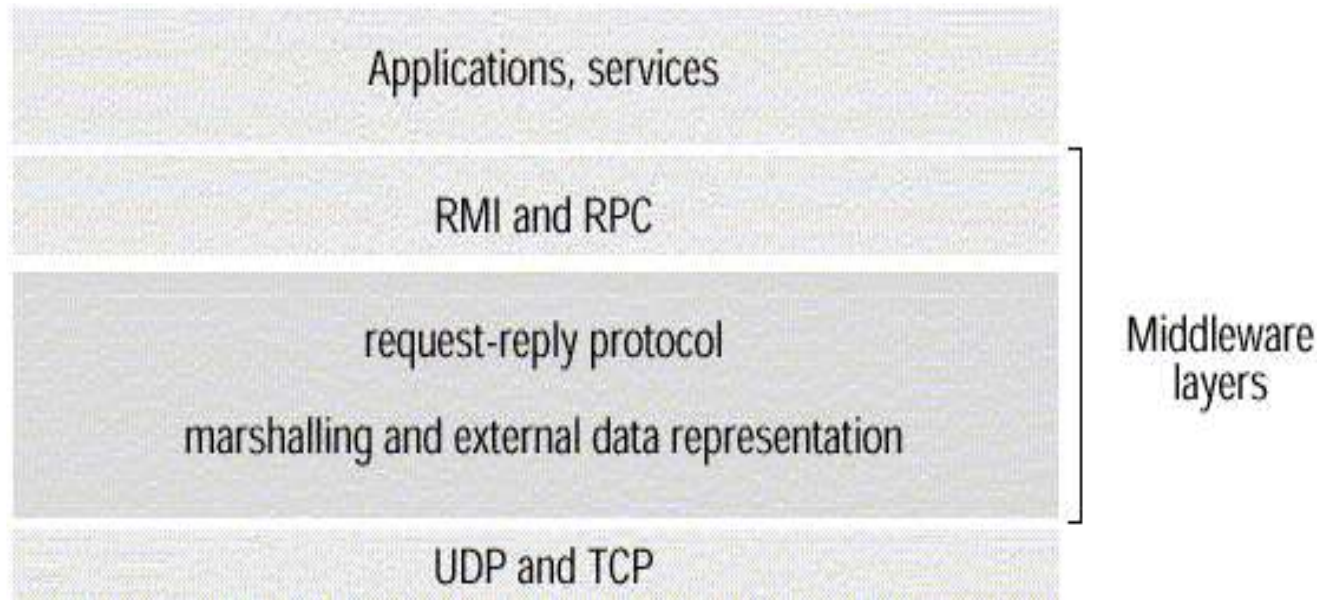

Figure 1. Middleware layers

Introduction

- Remote Method Invocation (RMI)

- It allows an object to invoke a method in an object in a remote process.

- ❖ E.g. CORBA and Java RMI

- Remote Procedure Call (RPC)

- It allows a client to call a procedure in a remote server.

Introduction

- The application program interface (API) to UDP provides a **message passing** abstraction.
 - Message passing is the simplest form of inter process communication.
 - API enables a sending process to transmit a single message to a receiving process.
 - The independent packets containing these messages are called **datagrams**.
 - In the Java and UNIX APIs, the sender specifies the destination using a **socket**.

Introduction

- **Socket** is an indirect reference to a particular port used by the destination process at a destination computer.
- The application program interface (API) to TCP provides the abstraction of a two-way stream between pairs of processes.
- The information communicated consists of a stream of data items with no message boundaries.

4.2 The API for the Internet Protocols

- The CHARACTERISTICS of INTERPROCESS COMMUNICATION
- SOCKET
- UDP DATAGRAM COMMUNICATION
- TCP STREAM COMMUNICATION

4.2.1 The Characteristics of Interprocess Communication

1. Synchronous and asynchronous communication

- In the synchronous form, both send and receive are **blocking** operations.

When a send is issued the sending process(or thread) is blocked until the corresponding receive is issued. When the receive is issued the process blocks until a message arrives

- In the asynchronous form, the use of the **send** operation is **non-blocking** and the **receive** operation can have **blocking** and **non-blocking** variants.

In non blocking variant the receiving process proceeds with its program after issuing a receive operation which provides a buffer in background but it must separately receive information that its buffer has been filled by polling or interrupt.

The Characteristics of Interprocess Communication

2. Message destinations

- A local port is a message destination within a computer, specified as an integer.
- A port has an exactly one receiver but can have many senders.

The Characteristics of Interprocess Communication

3. Reliability

- A reliable communication is defined in terms of **validity** and **integrity**.
- A point-to-point message service is described as reliable if messages are **guaranteed to be delivered** despite a reasonable number of packets being dropped or lost.
- For integrity, messages must arrive **uncorrupted** and **without duplication**.

4. Ordering: Some applications require that messages to be delivered in sender order.

4.2 Sockets

- A **socket** can be thought of as an endpoint in a two-way communication channel. Eg:telephone Call
- Internet IPC mechanism of Unix and other operating systems (BSD Unix, Solaris, Linux, Windows NT, Macintosh OS) Processes can **send** and **receive** messages **via a socket**.
- Sockets need to be bound to a **port number and an internet address** in order to send and receive messages.
- Each socket has a transport layer protocol (TCP or UDP).

Sockets

- Messages sent to some internet address and port number can only be received by a process using a socket that is bound to this address and port number.

IP Address + Port number = Socket

TCP/IP Ports And Sockets

Sockets

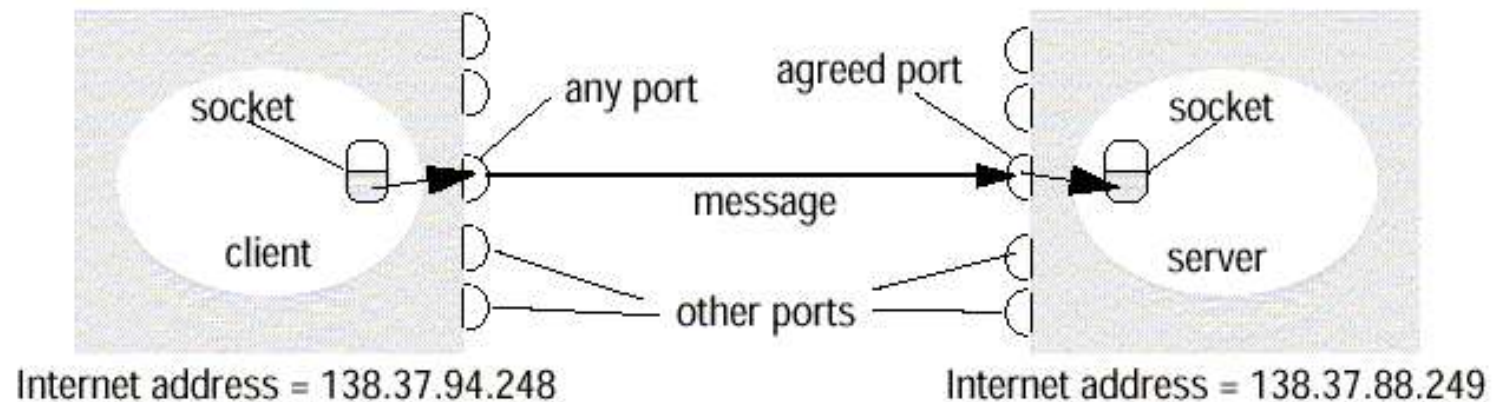

Figure 2. Sockets and ports

4.2.1 UDP Datagram Communication

- UDP datagram properties
 - No guarantee of order preservation
 - Message loss and duplications are possible
- Necessary steps
 - Creating a socket
 - Binding a socket to a port and local Internet address
 - ❖ A client binds to any free local port
 - ❖ A server binds to a server port
- Receive method
 - It returns Internet address and port of sender, plus message.

UDP Datagram Communication

- Issues related to datagram communications are:
 - Message size
 - ❖ IP allows for messages of up to 2^{16} bytes.
 - ❖ Most implementations restrict this to around 8 Kbytes.
 - ❖ Any application requiring messages larger than the maximum must fragment.
 - ❖ If arriving message is too big for array allocated to receive message content, truncation occurs.

UDP Datagram Communication

➤ Blocking

❖ Send: non-blocking

- upon arrival, message is placed in a queue for the socket that is bound to the destination port.

❖ Receive: blocking

- Pre-emption by timeout possible
- If process wishes to continue while waiting for packet, use separate thread

➤ Timeout

Timeout interval should be fairly large in comparison with the time required to transmit the message

➤ Receive from any

Receive method does not specify an origin for messages. The receive method returns the internet address and local port of the sender allowing the recipient to check where it came from.

UDP Datagram Communication

- Failure Model: UDP datagram's suffer from following failures:
 - Omission failure
 - Messages may be dropped occasionally
 - Ordering

Use of UDP: Acceptable to use a service that is liable to occasional omission failures. Ex DNS or VOIP. UDP data grams are preferred because they do not suffer from overheads associated with guaranteed message delivery

Java API for UDP Datagrams

- The Java API provides datagram communication by two classes:

- Datagram Packet

- ❖ It provides a constructor to make an array of bytes comprising:
 - Message content
 - Length of message
 - Internet address
 - Local port number

array of bytes containing message | length of message | Internet address | port number |

- ❖ It provides another similar constructor for receiving a message.

Java API for UDP Datagrams

➤ Datagram Socket

- ❖ This class supports sockets for sending and receiving UDP datagram.
- ❖ It provides a constructor with port number as argument.

- ❖ Datagram Socket methods are:
 - `send` and `receive`
 - `setSoTimeout`
 - `connect`

4.2.2 TCP Stream Communication

- The API to the TCP protocol provides the abstraction of a stream of bytes to be written to or read from.
- **Characteristics of the stream abstraction:**
 - Message sizes: Application may choose how much data it writes to stream or reads from it. The underlying implementation of a TCP stream decides how much data to collect before transmitting it as one or more IP packets.
 - Lost messages: The TCP protocol uses an acknowledgement scheme. Ex Sliding window scheme.

TCP Characteristics Cont..

Flow Control: The TCP attempts to match the speed of the processes that read from and write to the stream. If the writer is too fast, it is blocked till the reader has consumed sufficient data.

Message Duplication and Ordering: Message Identifiers are associated with each IP packet, which enables the recipient to detect and reject duplicates or to reorder messages that do not arrive in sender order.

Message Destinations: A pair of communicating processes establish a connection before they can communicate over a stream. Establishing a connection requires a Connect request followed by an accept request from server to client before any communication happens.

TCP Stream Communication

- Issues related to stream communication:
 - **Matching of data items:**

Two processes need to agree as to the contents of data transmitted over a stream. Ex int followed by double written by one process must be read in the same way.
 - **Blocking:** Use of Queue at destination Socket.

When a process attempts to read data from the input channel it will get data from the queue or it will block until data becomes available
 - **Threads:** Server creates a new thread when it accepts a connection for each client.

TCP Stream Communication

■ Use of TCP

➤ Many services that run over TCP connections, with reserved port number are:

- ❖ HTTP (Hypertext Transfer Protocol)
- ❖ FTP (File Transfer Protocol)
- ❖ Telnet
- ❖ SMTP (Simple Mail Transfer Protocol)

TCP Stream Communication

■ Java API for TCP streams

➤ The Java interface to TCP streams is provided in the classes:

❖ ServerSocket

- It is used by a server to create a socket at server port to listen for connect requests from clients.

❖ Socket

- It is used by a pair of processes with a connection.
- The client uses a constructor to create a socket and connect it to the remote host and port of a server.
- It provides methods for accessing input and output streams associated with a socket.
- It provides methods `getInputStream` and `getOutputStream` for accessing the 2 streams associated with a socket

4.3 External Data Representation

- The information stored in running programs is represented as data structures, whereas the information in messages consists of sequences of bytes.
- Irrespective of the form of communication used, the data structure must be converted to a sequence of bytes before transmission and rebuilt on arrival.

External Data Representation

- External Data Representation is an agreed standard for the representation of data structures and primitive values.
- Data representation problems are:
 - Using agreed external representation, two conversions necessary
 - Using sender's or receiver's format and convert at the other end

External Data Representation

- **Marshalling**
 - Marshalling is the process of taking a collection of data items and assembling them into a form suitable for transmission in a message.
- **Unmarshalling**
 - Unmarshalling is the process of disassembling a collection of data on arrival to produce an equivalent collection of data items at the destination.

External Data Representation

- Three approaches to external data representation and marshalling are:
 - CORBA
 - Java's object serialization
 - XML or Extensible Markup Language

External Data Representation

- Marshalling and unmarshalling activities is usually performed automatically by middleware layer.
- Marshalling is likely error-prone if carried out by hand.

4.3.1 CORBA Common Data Representation (CDR)

- CORBA Common Data Representation (CDR)
 - CORBA CDR is the external data representation defined with CORBA 2.0.
 - It consists 15 primitive types:
 - Short (16 bit)
 - Long (32 bit)
 - Unsigned short
 - Unsigned long
 - Float(32 bit)
 - Double(64 bit)
 - Char
 - Boolean(TRUE,FALSE)
 - Octet(8 bit)
 - Any(can represent any basic or constructed type)
 - Composite type are shown in Figure 8.

CORBA Common Data Representation (CDR)

<i>Type</i>	<i>Representation</i>
<i>sequence</i>	length (unsigned long) followed by elements in order
<i>string</i>	length (unsigned long) followed by characters in order (can also can have wide characters)
<i>array</i>	array elements in order (no length specified because it is fixed)
<i>struct</i>	in the order of declaration of the components
<i>enumerated</i>	unsigned long (the values are specified by the order declared)
<i>union</i>	type tag followed by the selected member

Figure 8. CORBA CDR for constructed types

CORBA Common Data Representation (CDR)

Figure 9 shows a message in CORBA CDR that contains the three fields of a **struct** whose respective types are **string**, **string**, and **unsigned long**.

example: struct with value {'Smith', 'London', 1934}

<i>index in sequence of bytes</i>		<i>notes on representation</i>
0–3	5	<i>length of string</i>
4–7	"Smit"	'Smith'
8–11	"h____"	
12–15	6	<i>length of string</i>
16–19	"Lond"	'London'
20–23	"on____"	
24–27	1934	<i>unsigned long</i>

Figure 9. CORBA CDR message

4.3.2 Java object serialization

- In Java RMI, both object and primitive data values may be passed as arguments and results of method invocation.
- An object is an instance of a Java class.
 - Example, the Java class equivalent to the Person struct

```
Public class Person implements Serializable {  
    Private String name;  
    Private String place;  
    Private int year;  
    Public Person(String aName ,String aPlace, int aYear) {  
        name = aName;  
        place = aPlace;  
        year = aYear;  
    }  
    //followed by methods for accessing the instance variables  
}
```

Java Serialization

To make use of Java Serialization

- Create an instance of class ObjectOutputStream
- Invoke writeObject method
- Pass person as argument

To deserialize

- Open ObjectInputStream
- Use readObject method (reconstruct original method)

Java object serialization

The serialized form is illustrated in **Figure 10**.

<i>Serialized values</i>				<i>Explanation</i>
Person	8-byte version number		h0	class name, version number
3	int year	java.lang.String name	java.lang.String place	number, type and name of instance variables
1934	5 Smith	6 London	h1	values of instance variables

Figure 10. Indication of Java serialization form

Extensible Markup Language

XML is a markup Language that was defined by the world wide web Consortium for general use on the web

Markup language refers to a textual encoding that represents both a text and details to its structure or its appearance. It is designed for writing structured documents for the web

XML data items are tagged with 'markup' tags.Th tags are used to describe the logical structure of the data and to associate attribute – value pairs with logical structures.

XML is used to enable clients to communicate with the web services and for defining the interfaces and other properties of web services.

It is extensible i.e users can define their own tags

Ex <person id="123456789">
 <name> Smith</name>
 <place>London</place>
 <year>1934</year>
 <!-- a comment --- >
</person>

Remote Object References

- Remote object references are needed when a client invokes an object that is located on a remote server.
- A remote object reference is passed in the invocation message to specify which object is to be invoked.
- Remote object references must be unique over space and time.

Remote Object References

- In general, may be many processes hosting remote objects, so remote object referencing must be unique among all of the processes in the various computers in a distributed system.
- generic format for remote object references is shown in **Figure 11**.

Figure 11. Representation of a remote object references

Remote Object References

- internet address/port number: process which created object
- time: creation time
- object number: local counter, incremented each time an object is created in the creating process
- interface: how to access the remote object (if object reference is passed from one client to another)

4.4 Client-Server Communication

- The client-server communication is designed to support the **roles** and **message exchanges** in typical client-server interactions.
- In the normal case, **request-reply** communication is **synchronous** because the **client** process **blocks** until the reply arrives from the server.
- **Asynchronous request-reply** communication is an alternative that is useful where **clients won't block** & can afford to retrieve replies later.

Client-Server Communication

- Protocol often built over UDP datagram's
 - UDP protocol avoids unnecessary **overheads** associated with **TCP**(Stream) protocol
 1. **acknowledgements** are **redundant**, since requests are followed by **replies**;(piggybacked Ack's)
 2. Avoidance of **connection establishment** overhead which involves two extra pairs of msg's.
 3. No need for **flow control** due to small amounts of data (arguments/results) are transferred
-

Client-Server Communication

- The **request-reply protocol** was based on a trio of communication primitives: **doOperation**, **getRequest**, and **sendReply** shown in Figure 12.
- Illustrates RMI example

Figure 12. Request-reply communication

Client-Server Communication

- **Figure 13** outlines the three communication primitives.

public byte[] doOperation (RemoteObjectRef o, int methodId, byte[] arguments)

sends a request message to the remote object and returns the reply.

The arguments specify the remote object, the method to be invoked and the arguments of that method.

public byte[] getRequest ();

acquires a client request via the server port.

public void sendReply (byte[] reply, InetAddress clientHost, int clientPort);

sends the reply message *reply* to the client at its Internet address and port.

Request Reply Protocol(cont..)

The request-reply protocol:

The protocol is based on a trio of communication primitives, *doOperation*, *getRequest* and *sendReply*,

This request-reply protocol matches requests to replies. It may be designed to provide certain delivery guarantees. If UDP datagrams are used, the delivery guarantees must be provided by the request-reply protocol, which may use the server reply message as an acknowledgement of the client request message.

The *doOperation* method is used by clients to invoke remote operations. Its arguments specify the remote server and which operation to invoke, together with additional information (arguments) required by the operation. Its result is a byte array containing the reply.

getRequest is used by a server process to acquire service requests.

sendReply is used to send the reply message to the client. When the reply message is received by the client the original *doOperation* is unblocked and execution of the client program continues.

Client-Server Communication

- The **information** to be transmitted **in a request message** or a **reply message** is shown in Figure 14.

messageType	<i>int (0=Request, 1= Reply)</i>
requestId	<i>int</i>
objectReference	<i>RemoteObjectRef</i>
methodId	<i>int or Method</i>
arguments	<i>// array of bytes</i>

Figure 14. Request-reply message structure

Client-Server Communication

- In a protocol message
 - The **first field** indicates whether the message is a **request or a reply** message.
 - The **second field request id** contains a message identifier.
 - A **message identifier** consists of **two parts**:
 - ❖ A **requestId**, which is taken from an increasing sequence of integers by the sending process
 - ❖ An **identifier for the sender process**, for example its port and Internet address
 - The **third field** is a **remote object reference** .
 - The **fourth field** is an **identifier for the method** to be invoked followed by **arguments**

Client-Server Communication

- Failure model of the request-reply protocol
 - If these **three primitives** are implemented over UDP they have the same **communication failures**

- Omission failure (link failures, drops/losses, missed/corrupt addresses)
- Out-of-order delivery
- Node/process down

Solved by

- Timeouts with retransmission until reply is received/confirmed
- Discards of repeated requests by requestId (by server process)
- On lost reply messages, server repeats idempotent operations(eg.adding an element to set)
- Maintain history (reqid, message, client-id) or buffer replies and retrans – memory intensive

Client-Server Communication

- RPC exchange protocols(failure handling)
 - Three protocols are used for implementing various types of RPC.
 - ❖ The request (R) protocol.
 - ❖ The request-reply (RR) protocol.
 - ❖ The request-reply-acknowledge (RRA) protocol.

(Figure 15)

Client-Server Communication

<i>Name</i>	<i>Messages sent by</i>		
	<i>Client</i>	<i>Server</i>	<i>Client</i>
R	<i>Request</i>		
RR	<i>Request</i>	<i>Reply</i>	
RRA	<i>Request</i>	<i>Reply</i>	<i>Acknowledge reply</i>

Figure 15. RPC exchange protocols

Client-Server Communication

- In the **R protocol**, a single request message is sent by the client to the server.
- The R protocol may be used when there is no value to be returned from the remote method.
- The **RR protocol** is useful for most client-server exchanges because it is based on request-reply protocol.
- **RRA protocol** is based on the exchange of three messages: request-reply-acknowledge reply.

Client-Server Communication

- HTTP: an example of a request-reply protocol
 - HTTP is a request-reply protocol for the exchange of network resources between web clients and web servers.
 - Client requests specify a URL that includes DNS Host name+Port no.+resource identifier on that port
 - HTTP Allows→Content Negotiation & Authentication
 - Content negotiation→ negotiating for appropriate data representations between client & server
 - Password Style Authentication

Client-Server Communication

- HTTP protocol steps for Client- Server interaction:
 - ❖ Connection establishment between client and server at the default server port or at a port specified in the URL
 - ❖ client sends a request
 - ❖ server sends a reply
 - ❖ connection closure

Client-Server Communication

- Need to establish & close connection for every request-reply exchange is expensive
- Request & reply are marshalled into msgs as ASCII text
- Resources can have MIME(Multipurpose Internet Mail Extension)-like structures in arguments and results
- Data is prefixed with Mime type so that recipient will know how to handle it
- **Mime type** specifies a type and a subtype, for example:
 - ❖ text/plain, text/html, image/gif, image/jpeg

Client-Server Communication

- HTTP methods
- Client Rqst=method+URL

➤ GET

- ❖ Requests the resource, identified by URL as argument.
- ❖ If the URL refers to data, then the web server replies by returning the data
- ❖ If the URL refers to a program, then the web server runs the program and returns the output to the client.

<i>method</i>	<i>URL</i>	<i>HTTP version</i>	<i>headers</i>	<i>message body</i>
GET	//www.dcs.qmw.ac.uk/index.html	HTTP/ 1.1		

Figure 16. HTTP request message

Client-Server Communication

➤ HEAD

- ❖ This method is similar to GET, but only meta data on resource is returned (like date of last modification, type, and size)
- ❖ i.e status line

Client-Server Communication

➤ POST

- ❖ Specifies the URL of a resource (for instance, a server program) that can deal with the data supplied with the request.
- ❖ This method is designed to deal with:
 - Providing a block of data to a data-handling process
 - Posting a message to a bulletin board, mailing list or news group.
 - Extending a dataset with an append operation

Client-Server Communication

➤ PUT

- ❖ Supplied data to be stored in the given URL as its identifier.

➤ DELETE

- ❖ The server deletes an identified resource by the given URL on the server.

➤ TRACE

- ❖ The server sends back the request message

➤ OPTIONS

- ❖ A server supplies the client with a list of methods.
- ❖ It allows to be applied to the given URL

Client-Server Communication

- A reply message specifies
 - ❖ The protocol version
 - ❖ A status code
 - ❖ Reason
 - ❖ Some headers
 - ❖ An optional message body

<i>HTTP version</i>	<i>status code</i>	<i>reason</i>	<i>headers</i>	<i>message body</i>
HTTP/1.1	200	OK		resource data

Figure 17. HTTP reply message

Client-Server Communication

■ Status codes

- 100 block → Informational → Eg. 103 – checkpoint
- 200 block → Success → Eg. 200-OK, 201-created
- 300 block → Redirection → Eg. 302-Found, 304-Not Modified
- 400 block → Client Error → Eg. 404-Not Found 408-Request Timeout
- 500 block → Server error → Eg. 500-Internal Server Error, 502-Bad Gateway, 503-Service Unavailable
